

Unity first open for TimberbornMods

Exact editor, required modules, project argument, and Modding Tools import

Goal

Prepare ModsUnityProject so it can compile and export Timberborn mod resources. Do not run batch compilation or export until the importer has created Assets/Plugins/Timberborn.

1

Use the exact project editor

Install Unity 6000.4.6f1. Do not substitute another 6000.x release, even if Unity Hub marks it Supported or LTS.

2

Install build support

Keep the Windows editor support and add Mac Build Support (Mono). Web Build Support and Windows IL2CPP are not required for this repository.

3

Add the existing project

In Unity Hub select Add > Add project from disk and choose D:\Work\TimberbornMods\ModsUnityProject.

4

Set the launch argument

In the project's Hub settings add exactly: -disable-assembly-updater

5

Complete the interactive import

Open the project, choose Ignore if Safe Mode is offered, and import from D:\SteamLibrary\steamapps\common\Timberborn.

Success gate

Assets/Plugins/Timberborn exists and contains imported/publicized game DLLs. Imported assets should appear under Assets/Tools/ImportedAssets.

Install the exact Unity Editor

Unity Hub > Installs (or install directly from the missing-version prompt)

Required version

6000.4.6f1 - the version recorded by ModsUnityProject/ProjectSettings/ProjectVersion.txt.

1

Open Unity Hub

Sign in and confirm that the license is active.

2

Install 6000.4.6f1

If the project shows Missing Editor Version, leave 6000.4.6f1 selected and click Install Version 6000.4.6f1.

3

Do not choose a nearby version

6000.3.19f1 and 6000.5.3f1 are different editors. Using one can rewrite project metadata or create incompatibilities.

If 6000.4.6f1 is already installed

Cancel the installer and make sure the project row in Hub is associated with that exact editor. Never upgrade the project during bootstrap.

Real screen: Build Support modules

Unity Hub 3.19.5 - installing Editor 6000.4.6f1

What to select

Mac Build Support (Mono) is correctly selected in the screenshot and is required for the Mac AssetBundle.

Uncheck the unnecessary module

Web Build Support is also selected in the screenshot, but TimberbornMods does not require it. Uncheck it unless you need WebGL; this saves about 4.14 GB. Windows support is part of the Windows editor. Windows Build Support (IL2CPP) is not required.

Add the project and configure its launch

Do this in Unity Hub before the first open

- 1 Add from disk**
Projects > Add > Add project from disk. Select D:\Work\TimberbornMods\ModsUnityProject, not the repository root.
- 2 Open project settings in Hub**
Use the project's context menu/settings and locate the command-line arguments or advanced launch arguments field.
- 3 Add one argument**
Enter exactly: -disable-assembly-updater
- 4 Verify the editor association**
The project must show Editor Version 6000.4.6f1.

Why the argument matters

The project imports Timberborn assemblies. Disabling Unity's automatic assembly updater prevents Unity from attempting to rewrite those external game assemblies during project startup.

Do not install a duplicate package

This checkout already tracks Assets/Tools/package.json for com.mechanistry.timberborn-modding. Do not add the alternative Git package on top of it.

Real screens: add the project

Unity Hub steps before the first project open

1. In Projects open Add and select Add project from disk. Choose D:\Work\TimberbornMods\ModsUnityProject.

2. If Hub reports Missing Editor Version, keep only 6000.4.6f1 selected and click Install Version 6000.4.6f1. Do not choose 6000.3.19f1 or 6000.5.3f1.

First interactive project open

Allow package resolution and complete the importer workflow

- 1 Launch from Unity Hub**
Open ModsUnityProject with 6000.4.6f1 and the saved -disable-assembly-updater argument.
- 2 If Safe Mode is offered**
Choose Ignore, not Enter Safe Mode. Missing Timberborn references are expected before the import completes.
- 3 Wait for Unity**
Let package resolution, script refresh, and initial asset discovery finish. Do not close the editor while progress indicators are active.
- 4 Open the Timberborn importer**
Use the Timberborn Modding Tools menu/window supplied by the tracked Assets/Tools package.
- 5 Select the game root**
Use D:\SteamLibrary\steamapps\common\Timberborn. Do not select Timberborn_Data or the repository's _GAME! link.
- 6 Import DLLs and assets**
Run the provided import actions and wait until Unity completes the following script reload.

Expected temporary errors

Before import, errors mentioning IAssetProvider or OrderedAsset can be caused by the absent game DLLs. The gate is the completed importer output, not a clean Console before import.

Verification checklist

Do not proceed to batch compilation or export until every required check passes

- 1 Editor**
Unity 6000.4.6f1 is running.
- 2 Launch argument**
-disable-assembly-updater is saved for the Hub project.
- 3 Modules**
Mac Build Support (Mono) is installed; Windows editor support is present.
- 4 Game DLLs**
ModsUnityProject/Assets/Plugins/Timberborn exists and contains imported/publicized assemblies.
- 5 Imported assets**
ModsUnityProject/Assets/Tools/ImportedAssets exists after the asset import.
- 6 Console**
After the final script reload, no unresolved Timberborn type/reference errors remain.

Stop condition

If Assets/Plugins/Timberborn is absent, do not try batch mode and do not export a mod. Reopen the importer, verify the selected game root, and capture the importer error or Console message.

Troubleshooting and completion

What to report if the first open does not reach the success gate

Hub cannot find the editor

Install exactly 6000.4.6f1 or associate the existing installation with the project. Do not open with another version.

Safe Mode appears

Choose Ignore. Then complete the Timberborn DLL/assets import in normal editor mode.

Importer cannot find Timberborn

Confirm the root is D:\SteamLibrary\steamapps\common\Timberborn and that Timberborn_Data is inside it. The Steam game must be installed locally.

Compilation still fails after import

Wait for the script reload to finish, clear the Console, and capture the first remaining error with its full stack trace. Also confirm Assets/Plugins/Timberborn is populated.

Ready

The setup is complete when the exact editor opens normally, required importer output exists, and the Unity Console no longer reports missing Timberborn references. At that point repository batch compilation/export may be tested.
